I. PROJECT SUMMARY

The applicant proposes to construct a 3-story self-storage facility, 120,750 square feet in total floor area, and associated site improvements on Lots 45.01 and 46.01, Block 502.01 along Davidson Avenue. The 10.997-acre tract previously included an one-story main building, several outbuildings, a large, looped driveway and a smaller driveway. The total impervious coverage from these existing and pre-existing site features is 0.6 acres.

The proposed self-storage facility will result in a total site impervious coverage of 2.08 acres. In order to mitigate the impact of the increase in runoff due to the further development of the site, a small-scale bioretention basin with extended detention storage volume is proposed to collect, treat, store and release, at a reduced rate, stormwater runoff from the developed portion of the site. This stormwater BMP has been designed in accordance with state and local stormwater management regulations for Green Infrastructure.

The majority of the site, approximately 7.5 acres, will remain undeveloped. This area consists of two streams, whose confluence is just downstream from the northerly property line, and their associated flood hazard areas and stream corridors. These areas will be protected from further development by environmental constraints. As required by the Delaware Raritan Canal Commission, a Non-Structural Strategies Point System (NSPS) Spreadsheet has been completed for this project (see Appendix F.) The NSPS spreadsheet shows that the site design incorporates sufficient low impact development strategies to address stormwater management. The design of the structural stormwater BMP and the overall stormwater management plan for this project are discussed in detail below.

II. DISCUSSION OF STORMWATER IMPACT

A. STORMWATER QUANTITY

The proposed development will result in an increase in on-site impervious area of approximately 1.5 acres. As such, measures must be taken to mitigate the impact of the resulting increase in stormwater runoff. In order to adequately design these measures, a hydrologic study of the site has been performed. The hydrologic analysis compares existing and proposed flows from the site, using a total area of analysis which encompasses the tract area up to the Davidson Avenue curb line (10.84 acres.)

In accordance with state and local stormwater regulations, the analysis of the stormwater runoff impact must reflect a reduction in flows after any improvements which increase runoff from the site. As such, the flow analysis includes the computation of "allowable" post development flows. These allowable flows are existing flow values with appropriate reduction factors applied to the undeveloped portion of the site which will be improved. The appropriate reduction factors are as follows: 50% for the 2-year frequency storm, 75% for the 10-year storm, and 80% for the 100-year storm. In the

case of this development, the reduction factors were applied to all existing pervious areas which will be disturbed. The reduction factors have not been applied to existing impervious areas, or those areas which will remain undisturbed.

In order to reduce the impact of stormwater runoff from the site, green infrastructure strategies are proposed as part of the development. The area of disturbance footprint is kept to a minimum by utilizing only the front portion of the site and avoiding environmentally sensitive areas to the greatest extent possible. The proposed conveyance system includes a drainage swale to help reduce the time of concentration and therefore the flow volume. Finally, a small-scale bioretention basin with sufficient storage volume to provide extended detention is proposed to control the quantity and quality of stormwater runoff. A small-scale bioretention basin, which meets the criteria for green infrastructure, has a maximum contributory drainage area of 2.5 acres. The proposed bioretention basin is located in Proposed Drainage Sub-Area #1a, which totals 2.9 acres. Per NJAC 7:8, the definition of "Contributory Drainage Area" (CDA) is "the area from which stormwater runoff drains to a stormwater management measure, not including the area of the stormwater management measure itself." Since the bioretention basin encompasses an area of 0.4 acres, the resulting CDA is 2.5 acres, thereby meeting the small-scale criteria to be considered green infrastructure per current NJDEP regulations.

The bioretention basin has been designed to reduce the site runoff to below allowable flow values. The site flows were developed using SCS methodology and HydroCAD modelling software. The complete output from the 2, 10 and 100-year HydroCAD models (allowable and proposed conditions) is located in Appendix B. The results of the hydrologic models are summarized in the tables below.

Summary of Site Flows:

ALLOWABLE FLOW (cfs)	Storm Frequency (years)		
	2	10	100
1a: Undeveloped Area to be Disturbed	1.96	4.61	10.43
<i>reduction factor applied</i>	0.5	0.75	0.80
RF: Reduced 1a Flow	0.98	3.45	8.34
1b: Previously Developed Portion of site	2.06	3.10	5.10
1c: Undeveloped Area to Remain	6.30	14.80	33.52
All: Total Allowable flow from site	8.11	19.54	44.05

PROPOSED FLOW	Storm Frequency (years)		
	2	10	100
1a: Proposed Flow to Basin	7.42	11.88	20.66
1P: Bioretention Basin Outflow	0.50	2.89	8.78
Basin Stage	55.06	55.60	56.46*
1b: Proposed Bypass Flow	6.75	15.72	35.49
PR: Total Proposed Flow from site	7.06	17.60	43.62

* The crest elevation of the Emergency Spillway is 56.50; therefore, the required 100-yr storm storage volume is contained within the basin.

As indicated in the tables above, the proposed bioretention basin will provide adequate storage volume to control the rate of runoff from the site to allowable flow levels.

In order to safely convey extraordinary flows from the basin, a 20-foot wide emergency spillway will be provided. The basin embankment is not classified as a dam; therefore, the adequacy of the spillway width was checked using a 100-year storm routing with the outlet structure/pipe blocked. The results of this model can be found in Appendix B and are summarized below:

Bioretention Basin – Emergency Spillway Storm 20'-wide Spillway – Crest @ 56.50	
100 yr Basin Inflow	20.66 cfs
Flow through Emergency Spillway	11.65 cfs
Peak Water Surface Elevation	56.86
Top of Berm Elevation	58.00

Since the peak water surface elevation of the model with flow through the emergency spillway is less than the top of berm elevation, the spillway is adequately sized. The 20-foot spillway is not in a fill area; as such, no spillway stabilization is proposed nor required.

B. STORMWATER QUALITY

In addition to providing quantity control, the proposed bioretention basin will provide water quality treatment for the site runoff. Stormwater runoff from the developed site will be filtered through the planted bed bottom. Per the NJDEP Stormwater BMP Manual, the bioretention basin as designed (24" thick planting bed with site tolerant grasses) will provide 80% TSS removal. The bioretention basin has been designed with an underdrain system since site soils do not provide sufficient recharge under existing conditions (see Section C for more information on soils testing results.) In order to design the BMP to provide adequate treatment, the water quality design storm was

routed through the basin to determine the invert of the lowest quantity control outlet, consistent with best management practices. This model is located in Appendix C and is summarized in the table below:

Bioretention Basin – WQ Storm	
Water Quality Inflow	5.46 cfs
Water Quality Outflow	0.21*
WQ Water Surface Elev.	53.92
Depth of Peak Storage	11 inches

* This outflow value for the WQ storm represents the flow conveyed by the underdrain system after filtration through the bioretention basin soil bed.

The lowest outlet, a 4" orifice, is set just above the peak water surface elevation, at 53.95. Therefore, the entire water quality design storm will be filtered through the soil bed. An analysis of the time to drain the WQ volume indicates that the stored runoff will drain in approximately 15 hours (see calculations in Appendix C.)

C. GROUNDWATER RECHARGE

An investigation of the permeability of the onsite soils has been performed. Four full depth test pits were excavated to assess the soil parameters, including the ability of the soil to infiltrate stormwater. Additional areas on the site were preliminarily assessed in order to attempt to find a favorable location for a potential recharge BMP. As described in the Soils Testing Summary provided in Appendix D of this report, the permeability of existing on-site soils was found to be immeasurable. This negligible permeability indicates that onsite soils do not currently allow for any significant infiltration of stormwater. Therefore, it can be concluded that negligible groundwater recharge is being provided under existing conditions. As such, no structural stormwater management measures to prevent the loss of groundwater recharge are required as part of this proposal.

Since the runoff collected in the proposed stormwater management facility is not intended to provide groundwater recharge, an underdrain system will be constructed in the bottom of the bioretention basin, below the planting bed. This underdrain system will convey the filtered stormwater to the outlet structure to discharge with the runoff stored and released by the detention basin.

III. STORMWATER CONVEYANCE SYSTEM DESIGN

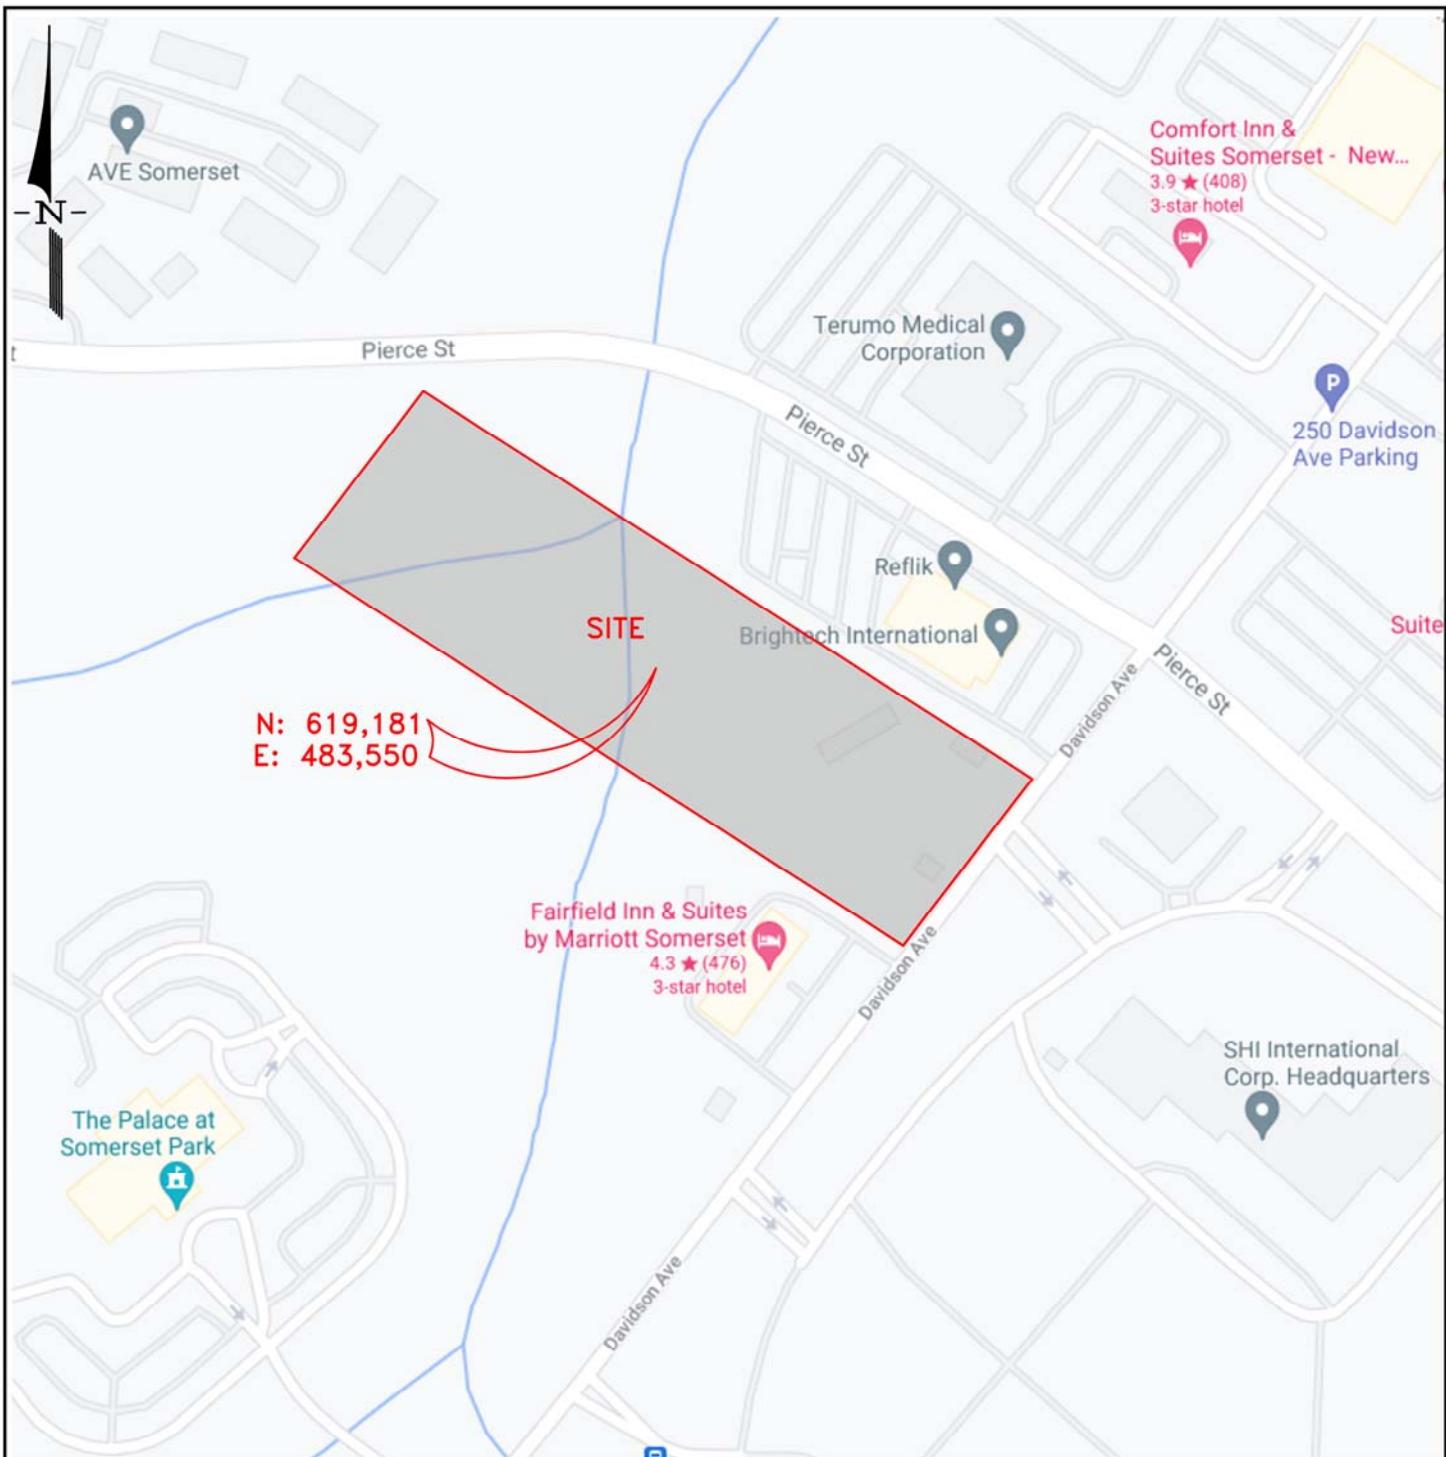

Calculations supporting the design of the proposed stormwater conveyance system are in Appendix E of this report. The inlet flows were computed using the Rational Method and cumulative pipe flows are compared to pipe capacity. A 100-year design storm was

utilized for the entire system as there are critical pipe runs towards the upstream end of the system. Inlet drainage areas are shown on map DA-3.

The design of the stormwater management basin reflects New Jersey's Standards for Soil Erosion and Sediment Control. Calculations supporting the size of the conduit outlet protection (riprap aprons) provided at the detention basin inflow and outlet pipes are also located in Appendix E.

APPENDIX D

SOILS INVESTIGATION RESULTS

SOIL TESTING SUMMARY
for
297 & 305 Davidson Avenue
Block 502.01 - Lot(s) 45.01 & 46.01
Franklin Township, Somerset County

Soils testing was performed at the project site on June 27, 2021. Four full soil profile pits were conducted (Test Areas 1-4) for the purpose of analyzing areas for potential infiltration BMPs; additional areas were preliminarily investigated but rejected for obvious lack of permeability and evidence of high groundwater table. The test pit areas are shown on the location map provided in this appendix.

Soil testing was performed by using a track excavator with hammer to excavate an approximately 5' by 10' area to a maximum depth of 12 feet, where possible. Soil parameters with each pit were logged based on the USDA textural triangle, the Munsell system of classification, among other standard practices for soil log data (see soil log profile data sheets provided in this appendix.) Any seepage within the pit was noted and evaluated. Soil hydraulic conductivity testing was conducted where feasible, in accordance with Chapter 12 of the NJ Stormwater Management BMP Manual. See the descriptions below of each full test pit additional information regarding permeability testing. Any observance of the seasonal high groundwater table is noted in the soil log profile sheets.

Test Pit Area#1

Slight seepage was encountered at 72" depth. A total of 2" of water had accumulated over a 24-hour period, which is not enough water to perform a Pit-Bail Test. Due to the presence of some seepage, no outside water could be introduced into the hole for the option of a permeability calculation. The shale is tightly layered and infilled with a clay loam, indicating poor conditions for positive drainage/recharge in this area, especially when the soils swell when they are wet.

Test Pit Area#2

No Groundwater was encountered during excavation. The pit was prepared for testing, to a width of 5ft, a length of 10ft and a depth of 48"(4ft). Water (375gallons - 12" deep) was introduced into the hole at that time. No drop in water elevation was observed after the required period of 24 hours. Therefore, no passing permeability could be achieved. The tightly layered shale infilled with the clay loam, helped verify this poor draining condition.

Test Pit Area#3

No Groundwater was encountered during excavation. The pit was prepared for testing to a width of 5ft, a length of 10ft and a depth of 56"(4.67ft). Water (375gallons - 12" deep) was introduced into the

hole at that time. There was no drop in water elevation after the required 24-hour period. Therefore, no passing permeability could be achieved. The presence of mottles (indicating perched water) in the test pit along with the tightly layered shale infilled with the clay loam, solidified this evidence of extremely poor draining/recharging condition in this area.

Test Pit Area#4

Slight seepage was encountered at 50". A total of 8 1/2" of water had accumulated over a 24-hour period. That again, is not sufficient water to perform a Pit-Bail Test. Due to the presence of seepage, no outside water could be introduced into the hole for the option of a permeability calculation. The presence of mottles (indicating perched water), combined with the tightly layered shale (infilled with a clay loam), indicate a poor chance for positive drainage/recharge when the soils swell when they are wet.

In Summary, each of these test pits had tightly layered shale along with clay loam which is typical of soils in this area along Davidson Avenue. The geotechnical analysis indicates that the site soils exhibit the properties associated with HSG D soils. The tests conducted confirmed results in this soil type that sufficient permeability is not available.

Historically, site soils with these same D-soil characteristics have been encountered in this area of Franklin Township. We have prepared designs for the adjoining hotel site (to the south) as well as the roadway project which connected Pierce Street at Davidson Avenue to Elizabeth Avenue. Further north we prepared the site plan for the office at the southwest corner of Davidson Avenue and Franklin Square Drive. Each of these sites had soil material similarly described – tightly layered shale with clay.

ANTI-SEEP COLLAR CALCULATIONS

Per NJAC Title 5, Chapter 21, the following criteria shall be used to determine size and number of anti-seep collars:

Let V = vertical and horizontal projection of anti-seep collar in feet,

Let L = length in feet of the zone of saturation, and

Let n = number of anti-seep collars.

The ratio of $(L + 2nV) / L$ shall be at least 1.15.

Collars shall be spaced at a distance of not more than 25 feet.

For the proposed Infiltration/Extended Detention Basin,

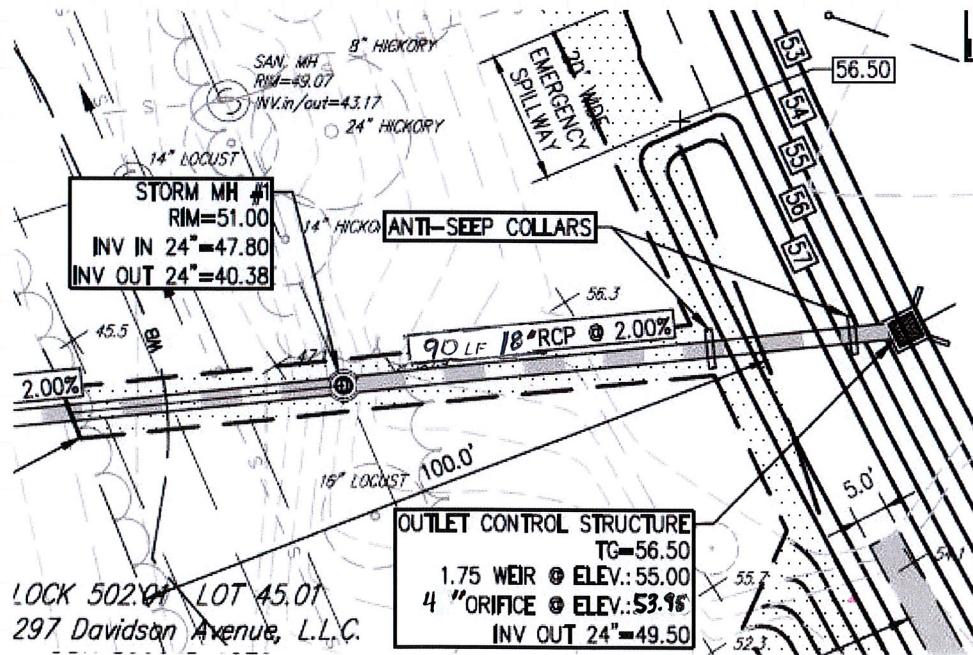

$$V = 2.0 \text{ feet}$$

$$L = 53 \text{ feet}$$

$$n = 2$$

$$(L + 2nV) / L = (53 + 2*2*2.0) / 53 = 61/53 = 1.151 > 1.15 ,$$

Therefore, 2 collars with a 2-foot projection in each direction are adequate.

Specify Source of Maximum Allowable Impervious Coverage:

Table	(None or Table)
-------	-----------------

Allowable Site Impervious Cover from Maximum Impervious Cover Table:

85%

Note: See Maximum Impervious Cover Table Worksheet for Details

Points Subtotal: 36

C. Compare Proposed Site Disturbance with Maximum Allowable Site Disturbance:

Total Proposed Site Disturbance =
Maximum Allowable Site Disturbance by Municipal Ordinance =

32%	% of Site
100%	% of Site

Points Subtotal: 31

D. Describe Proposed Runoff Conveyance System:

Total Length of Runoff Conveyance System =
Length of Vegetated Runoff Conveyance System =
% of Total Runoff Conveyance System That is Vegetated =

640	Feet
170	Feet
27%	

Points Subtotal: 24

E. Residential Lot Clustering:

Percent of Total Site Area that will be Clustered =
Minimum Standard Lot Size as Per Zoning (Note: 1/2 Acre or Greater) =
Maximum Proposed Cluster Lot Size (Note: 1/4 Acre or Less) =
Percent of Clustered Portion of Site to be Preserved as Vegetated Open Space =

	% of Site
	Acres
	Acres
	% of Clustered Site Portion

Points Subtotal: 0

F. Will the Following be Utilized to Minimize Soil Compaction?

Proposed Lawn Areas will be Graded with Lightweight Construction Equipment:
Percent of Proposed Lawn Areas to be Graded with Such Equipment:

Yes	(Yes or No)
25%	% of Lawn Areas

Points Subtotal: 6

G. Are Any of the Following Stormwater Management Standards Met Using Only Nonstructural Strategies and Measures?

Groundwater Recharge Standards (NJAC 7:8-5.4-a-2):
Stormwater Runoff Quality Standards (NJAC 7:8-5.5):
Stormwater Runoff Quantity Standards (NJAC 7:8-5.4-a-3):

No	(Yes or No)
No	(Yes or No)
No	(Yes or No)

Points Subtotal: 0

Note: If the Answers to All Three Questions at G Above are "Yes", Adequate Nonstructural Measures have been Utilized.

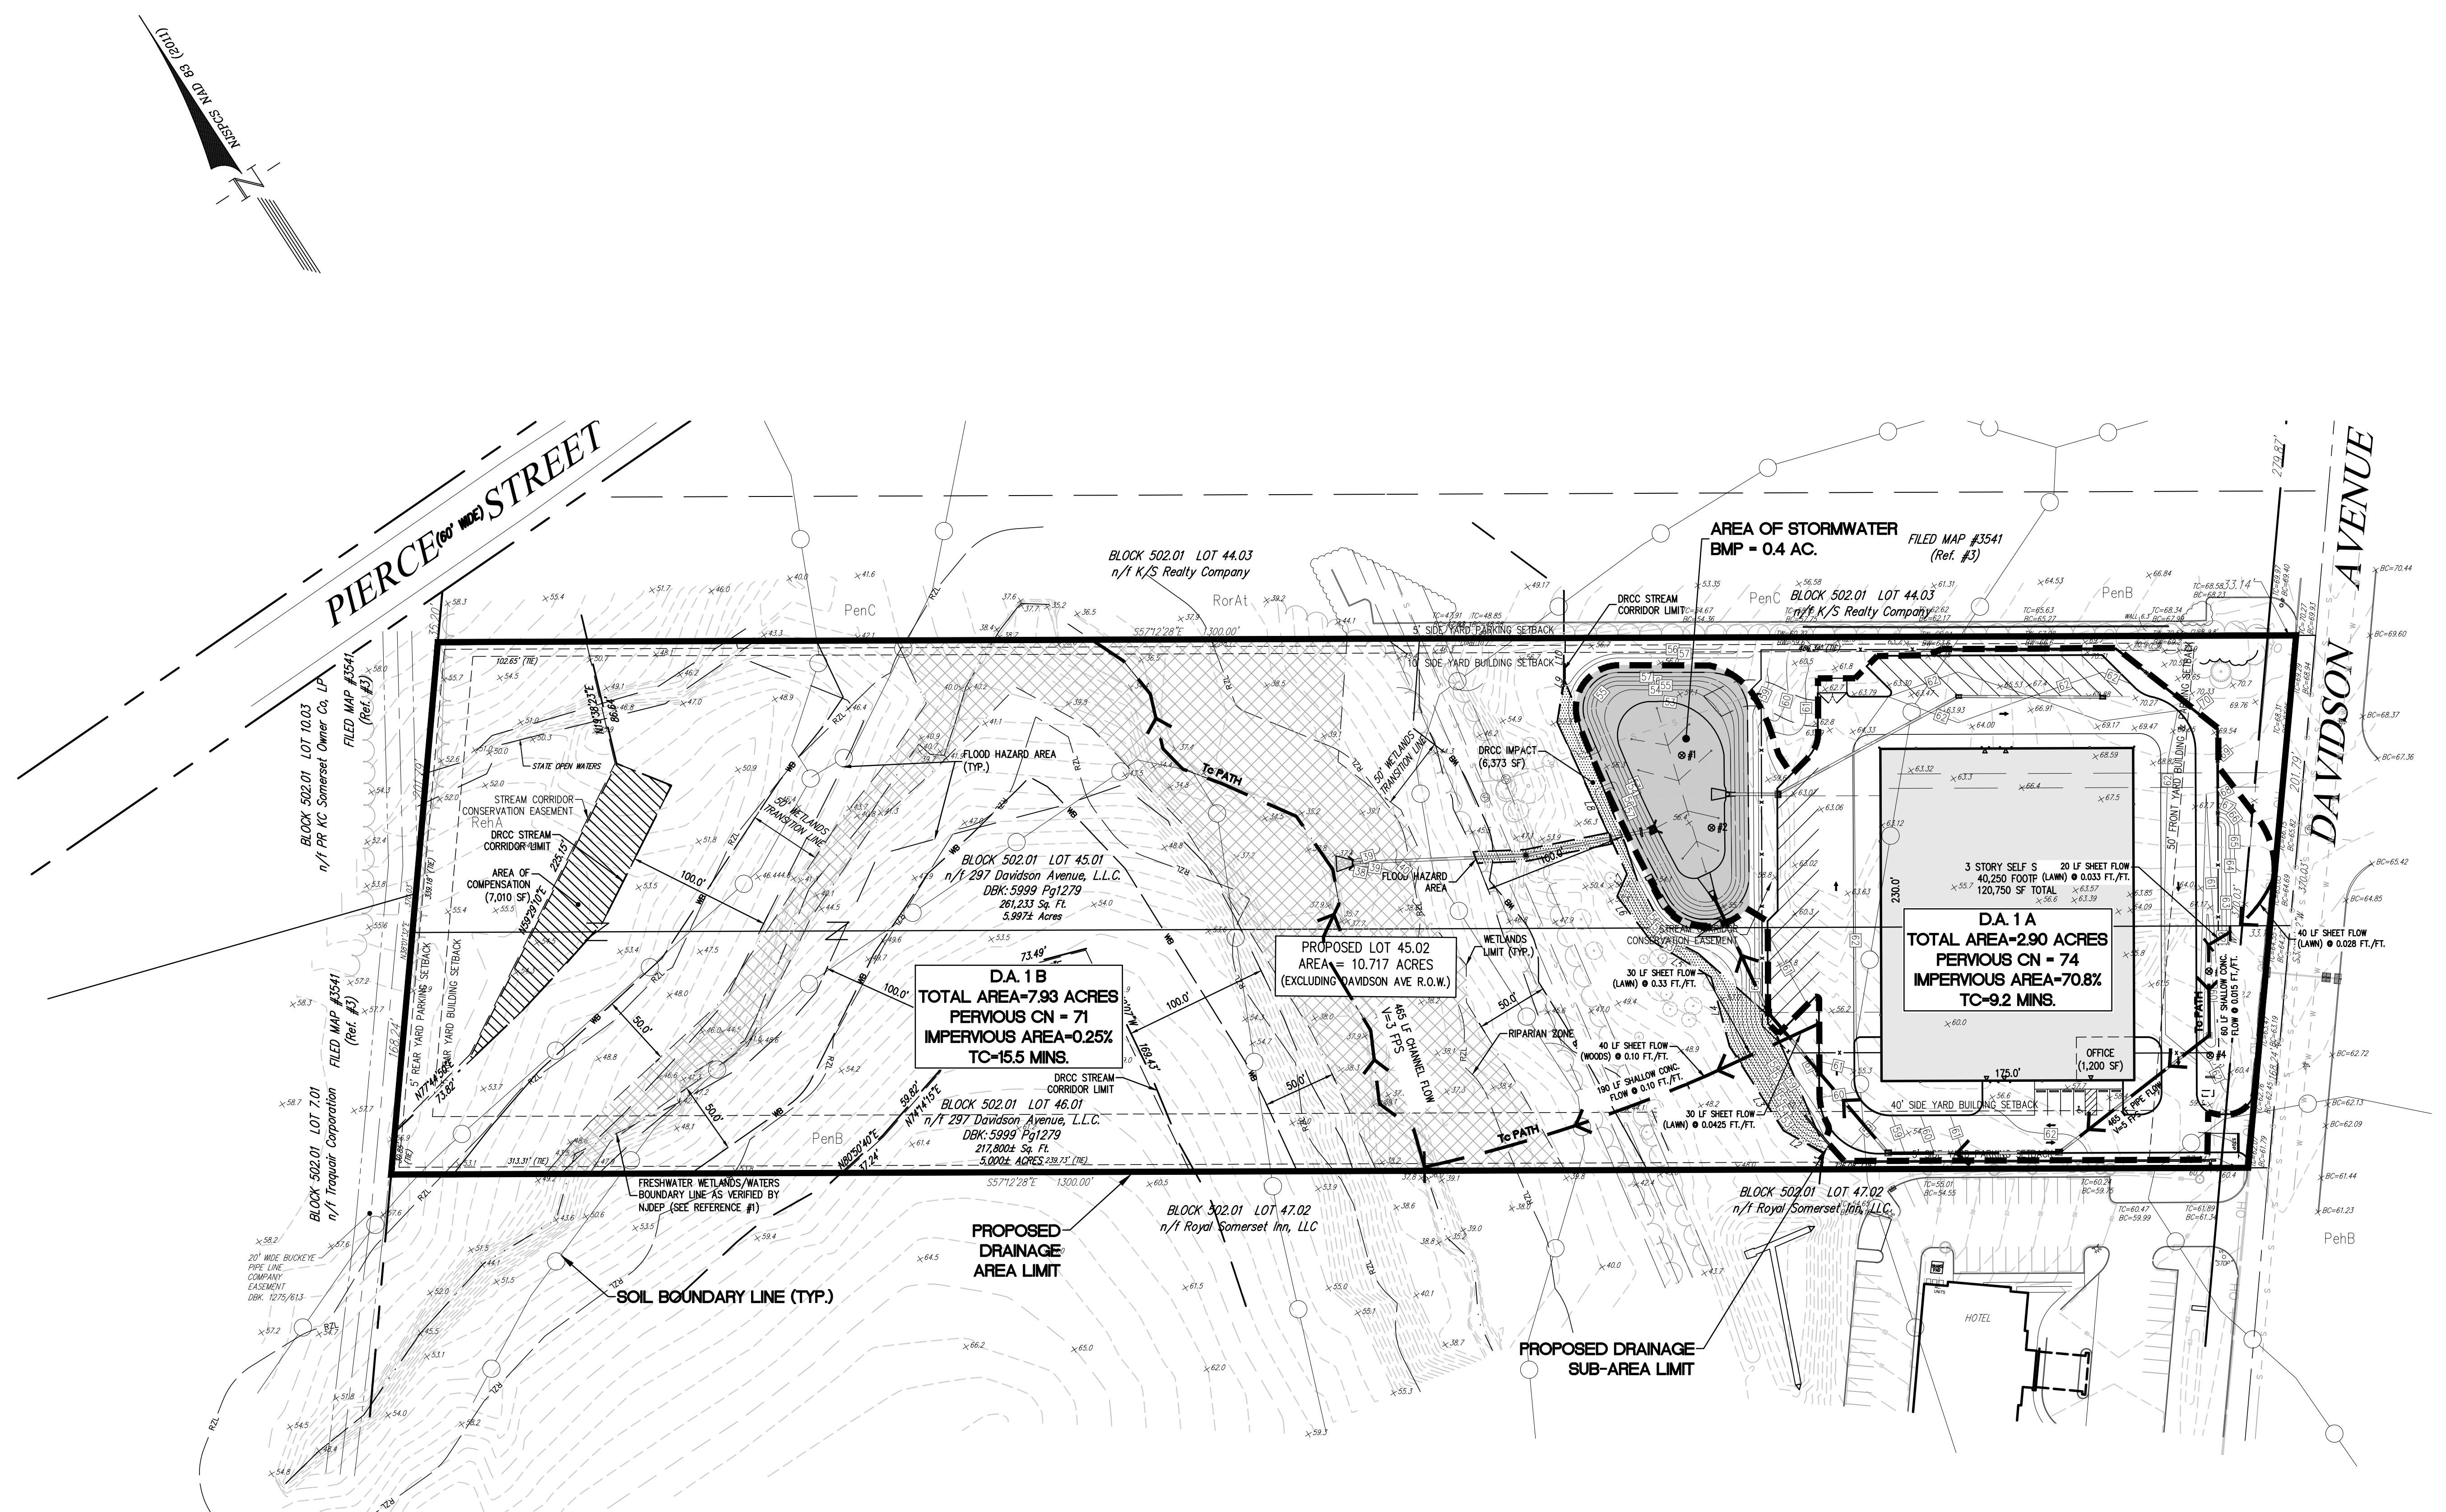

Total Proposed Site Points: 341

Ratio of Proposed to Existing Site Points: 114%

Required Site Points Ratio: 80%

Nonstructural Point System Results:

Proposed Nonstructural Measures are Adequate

CONTRIBUTORY DRAINAGE AREA
FOR BIORETENTION BASIN = 2.5 ACRES*

* PER NJAC 7:8-12, CONTRIBUTORY DRAINAGE AREA OF STORMWATER BMP EQUALS TOTAL DRAINAGE AREA, NOT INCLUDING AREA OF THE STORMWATER MANAGEMENT MEASURE ITSELF.

GRAPHIC SCALE

(IN FEET)

1 inch = 60 ft.
